

COMMAND — See It Yourself

A step-by-step guide to checking every fix and feature on your own instance. No technical knowledge needed. Just open the links and look at the screen.

Before you start

Everything below happens inside your ServiceNow instance. You only need a web browser and your normal ServiceNow login.

Your instance address is: **`https://dev390988.service-now.com`**

Every link in this guide starts with that address. For example, if the guide says `/cmd_catalog.do`, you type:

```
https://dev390988.service-now.com/cmd_catalog.do
```

Tip: log in to ServiceNow first in one browser tab. Then paste these links into the address bar of that same tab.

Check 1 — The home page (report list)

Step 1. Open this link:

```
/cmd_catalog.do
```

What you should see: a page of cards. Each card is a table you can analyse, with the number of records in it. This is the starting point for everything else.

Step 2. Click the **"Saved reports"** tab at the top.

What you should see: your existing ServiceNow reports, grouped by which table they read. There is a search box and page numbers at the bottom.

Step 3. Type a word into the search box (for example `incident`) and press Enter.

What you should see: the list narrows to matching reports. **This is the fix for large instances.** The search runs on the server, so it looks through all 682 reports, not just the ones on the current page. This is what makes 100,000+ reports work.

Step 4. Scroll to the bottom and click **Next**.

What you should see: the next page of reports. Before this fix, only the first 300 reports could ever be reached. Now every report is reachable.

Check 2 — The loading skeleton (the "pattern" you asked about)

Step 1. Go back to `/cmd_catalog.do`.

Step 2. Click any card, and **watch the screen carefully at the moment you click**.

What you should see: the page immediately turns into grey placeholder blocks shaped like the dashboard that is loading — a title bar, three boxes at the top, then a grid of chart panels. A soft shine moves across them. Then the real dashboard replaces it.

If it goes past too fast: pick a bigger table, like **Incident**. Bigger tables take longer to build, so the skeleton stays visible longer. You can also press **Ctrl+Shift+R** to force a fresh load.

Step 3. Try it in the other direction. From a dashboard, click **"All subjects"** at the top.

What you should see: a different skeleton shape — a row of card outlines, because you are going to the card page, not a dashboard. The skeleton always matches the page you are going to.

Check 3 — Drill down, 3 levels

Step 1. Open the Incident dashboard:

```
/cmd_dashboard.do?table=incident
```

Step 2. Find any chart and **click one of the bars or slices**.

What you should see: the whole page reloads, now showing only that group of records. At the top you will see a bar saying **"Filtered to"** with your choice listed next to it.

Step 3. Click a bar on another chart. Then do it once more.

What you should see: the "Filtered to" bar grows each time. You have now gone down 3 levels. After the third one, the charts stop offering more drilling. This is the built-in 3-level limit.

Step 4. Click the small **×** next to any one filter in that bar.

What you should see: that one filter is removed and the others stay. Clicking **"Clear all"** removes all of them.

Step 5. Copy the web address from your browser and paste it into a new tab.

What you should see: exactly the same filtered view. This is how you share a specific view with a colleague. The browser Back button also reverses each step.

Testing the drill-down limit yourself

You can try to break it. Paste this address, which asks for 5 levels instead of 3:

```
/cmd_dashboard.do?table=incident&path=priority:1|state:1|category:inquiry|impact:1|urgency:1
```

What you should see: the page opens normally, and the "Filtered to" bar shows **only 3 filters**, not 5. The extra two are ignored safely. There is no error message and no broken page.

Check 4 — Changing the chart type

Step 1. On any dashboard, find a chart panel and click the **"Chart"** button in its corner.

What you should see: a small menu opens with three parts:

- At the top: which chart type is being used now, and the reason it was picked.
- In the middle: other chart types you can switch to, each with its own reason.
- At the bottom, under **"Not offered for this data"**: chart types that were rejected, and why. For example, a pie chart is rejected when there are too many categories to read.

Step 2. Click one of the alternatives.

What you should see: only that one panel redraws in the new style. The rest of the page stays the same. The web address changes too, so you can share your chosen view.

Step 3. Open the "Chart" menu again.

What you should see: the button now says **"Chart: yours"**, and there is a new option at the top: **"Use what the data chose"**. Click it to go back to the automatic choice.

Check 5 — Security: what a different user can see

This is the most important check, and it answers your question about users in different regions.

Part A — Look at the access badge

Step 1. Open any dashboard, for example `/cmd_dashboard.do?table=incident`.

Step 2. Look near the record count at the top of the page for a small coloured badge.

If the badge says	It means
ACL verified (green)	You can read every record counted on this page. Nothing is hidden from you.
Filtered to your access (amber)	Some records exist that you are not allowed to read. They are excluded from every number on this page. Hover over the badge to see how many.
Counts are a lower bound (amber)	The table is very large, so we stopped counting after a time limit to keep the page fast. The real number may be slightly higher. It is never lower.
No access (red)	You cannot read any records in this table.

As an admin you will usually see the green badge, because admins can read everything. To see the other badges, do Part B below.

Part B — Log in as a normal user and compare

This is the real proof. We created two test accounts on your instance for exactly this.

Test account	What it represents
<code>cmd.itil.persona</code>	A normal service desk user with the standard "itil" role.
<code>cmd.test.restricted</code>	A user with no roles at all — the most limited case.

Step 1. While logged in as admin, use ServiceNow's **Impersonate User** feature. Click your profile picture in the top right corner, then choose **Impersonate User**, and pick `cmd.test.restricted`.

Step 2. Now open the report list:

```
/cmd_catalog.do?view=reports
```

What you should see: a much shorter list than you saw as admin — around 79 reports instead of 682. **Reports on tables this user cannot read are not shown at all.** They are not shown something they would then be blocked from opening.

Step 3. Now try to open a table this user is fully blocked from:

```
/cmd_dashboard.do?table=problem
```

What you should see: the page opens normally, but shows **0 records** and a clear sentence explaining that this table holds records but your permissions do not allow any of them. **You should not see any problem records, and you should not see an error or a crash.**

Step 4. Now compare the numbers. Still impersonating, open:

```
/cmd_dashboard.do?table=incident
```

What you should see: a much smaller record count than the 4,266 you see as admin — roughly 800 records — and the amber **"Filtered to your access"** badge. This is the key point: **the numbers on the charts only count records this user is allowed to open.**

Step 5. Click **"Open record list"** at the top of that page.

What you should see: ServiceNow's own standard list view opens, showing the same records. This proves our number matches what ServiceNow itself allows this user to see.

Step 6. Stop impersonating (profile picture, then **End Impersonation**) and open the same page again as yourself.

What you should see: the full 4,266 records and the green badge. **The same page, the same link, two different users, two different and correct answers.**

Please note what this does and does not prove. This shows that COMMAND enforces the access rules your instance already has, including rules that block an entire table and rules that allow only some rows within a table. Your development instance does not currently have region or company restrictions set up, so **this specific test is not a region test**. A region rule is the same kind of rule and is applied the same way, so we expect the same result — but we have not demonstrated it, and we will not change security settings on your instance to do so without your approval. We are happy to set this up on a test instance and show you.

Check 6 — Reports open live, with no stored copy

This proves that we never keep a separate copy of your reports.

Step 1. In COMMAND, open `/cmd_catalog.do?view=reports` and click any report. Note what it shows.

Step 2. Click **"Open the original report"**. This opens that report in ServiceNow's own report builder, in a new browser tab.

Step 3. Change the report's filter there and save it.

Step 4. Go back to COMMAND and open that same report again.

What you should see: your change is already applied. You did not need to re-import or refresh anything. **This is because we read the report live from ServiceNow every time and never store a copy.**

Check 7 — Try to break it

You are welcome to test these yourself. All of them should fail safely.

Paste this address	What should happen
<code>/cmd_dashboard.do?table=not_a_real_table</code>	A clear message saying that table does not exist. No crash, no technical error page.
<code>/cmd_dashboard.do? table=incident&path=fake_field:1</code>	The page opens normally with no filter applied. The invalid field is ignored.
<code>/cmd_dashboard.do? report=00000000000000000000000000000000dead</code>	A clear message that the report does not exist or you may not open it.
<code>/cmd_catalog.do?view=reports&offset=999999</code>	The page opens safely with no results. No error.
<code>/cmd_dashboard.do?table=incident&months=9999</code>	The time window falls back to the normal 12 months. Only 3, 6, 12 and 24 are accepted.

In every case the page should stay usable and should never show a technical error, a stack trace, or data you are not allowed to see.

If something does not look right

- **The page looks unstyled or the skeleton does not appear:** your browser is showing an old cached copy. Press **Ctrl+Shift+R** to force a fresh load.
- **A page is slow to open:** this is real, and we are not hiding it. Large tables are slow, and it gets worse when several people use it at once. We have measured this — see point 7 of the main report for the exact numbers, the reason, and the work we recommend before a wide rollout.
- **You see "Counts are a lower bound":** this is normal on very large tables. The number shown is real but may be slightly low, never high.
- **A number looks wrong:** click **"Open record list"** on that page. That opens ServiceNow's own list view with the same filter, so you can check our number against the platform directly.
